

MAMMAL NEURONAL ACID SENSING CATIONIC CHANNEL, CLONING
AND APPLICATIONS THEREOF

Sub 17 The present invention relates to a new family of mammalian, notably
human, acidity-sensitive ionic channels. More particularly, the invention
5 relates to the identification and molecular characterization in humans and
rats of a new proton-activated cationic channel referred to below as "ASIC" to
designate the English-language term "Acid Sensing Ionic Channel". The
ASIC channel constitutes the first member of a group of cationic channels, be-
longing to the family of amiloride-sensitive degenerine sodium channels [6,
10 11-14], which is activated temporarily by extracellular acidification.

Sensitivity to acid is associated with both nociception [1] and the transduc-
tion of taste [2]. The stimulation of sensory neurons by acids is of great impor-
tance because acidity accompanies numerous painful inflammatory and
ischemic situations. The pain caused by acids is interpreted as being mediated
15 by the cationic channels present at the level of the sensory neurons and
which are activated by protons [3-5]. The biophysical and pharmacological
properties of the ASIC channels of the invention are close to those of the pro-
ton-activated cationic channels described in the sensory neurons [3, 15, 16].
However, as will be seen in the description below, to date there has been no
20 report of ligand-activated ionic channels simpler than the ASIC channels.

Thus, the present invention has as its object a protein constituting a neu-
ronal cationic channel sensitive to amiloride and activated by protons. More
specifically, the invention relates to the protein constituting the ASIC chan-
nel, the amino acid sequence of which is represented in the annexed list of se-
quences under number SEQ ID NO: 2 or a functionally equivalent derivative
AA 25 of this protein.

Such derivatives are those whose sequence includes a modification and/or a suppression and/or an addition of one or more amino acid residues, as long as this modification and/or suppression and/or addition does not modify the functional and structural properties of the ASIC channel, principally its activation by protons. Such derivatives can be analyzed by the expert in the field using the techniques described in the examples presented below which made it possible to demonstrate the biophysical and pharmacological properties of the ASIC channel.

AA 10 An example of such a functionally equivalent derivative is the human
 AA ASIC protein, the amino acid sequence of which is represented in the annexed list of sequences under number SEQ ID NO: ⁴~~2~~, and which is approximately identical to that of the ASIC channel of the rat, designated ASIC1A, represented in the annexed list of sequences under number SEQ ID NO: 1.

15 Another example of such a functionally equivalent derivative is the protein constituting a cationic channel of degenerine designated "MDEG" [14] or "BNaCl" [20] or designated below as "ASIC2A" or "MDEG1", the amino acid sequence of which is represented in the annexed list of sequences under number
 AA 20 SEQ ID NO: ⁶~~3~~. MDEG has been described as a mammalian cationic channel sensitive to amiloride which is activated by the mutations responsible for neurodegeneration with the degenerines of *C. elegans*. The MDEG channel is a structural relative of the ASIC channel, the amino acid sequence of which exhibits circa 67% homology with the ionic channel MDEG. However, the electrophysiological properties of these two channels are different because they are not activated by the same pH changes. Thus, the range of
 25 sensitivity of MDEG ($EC_{50} = 4.05$) is different from that of ASIC ($EC_{50} = 6.2$).

It has been shown that the MDEG channel is activated by the same mutations as those causing neuronal degeneration in *C. elegans*. Thus, like the

hyperactive degenerine mutants of *C. elegans*, the active mutants of MDEG are responsible for a cell death, indicating that the acquisition of function by this neuronal ionic channel could be implicated in various forms of neuronal degeneration of mammals, notably of humans. However, no normal
 5 physiological function of MDEG was known until the demonstration of its activation by protons in accordance with the cationic channels of the present invention.

Other examples of proteins constituting a neuronal cationic channel that is sensitive to amiloride and activated by protons according to the invention
 10 are presented below:

– A channel designated ASIC1B, whose sequence of 559 amino acids is
 AA represented in the annexed list of sequences under number SEQ ID NO: ~~4~~⁸.
 ASIC1B is a splicing variant of the ASIC1A channel cloned from the rat brain by degenerated PCR. The first 185 amino acids are replaced by a new sequence
 AA 15 of 218 amino acids which is underlined in SEQ ID NO: ~~4~~⁸.

– A channel designated DRASIC, whose sequence of 533 amino acids is
 AA represented in the list of sequences under number SEQ ID NO: ~~4~~¹⁹. DRASIC was cloned from sensory neurons from the rat using a partial sequence from the data banks ("Expressed Sequence Tag" with accession number W62694).

20 The properties of DRASIC are as follows:

– It is expressed in the sensory neurons but not in the brain.

– Its expression in *Xenopus* oocytes or in mammal cells allows recording of a proton-activated sodium current which presents two components: a component activating and inactivating itself rapidly and a component activating itself more slowly and not inactivating itself. The two components are selective for Na⁺. A proton-activated cationic channel that does not inactivate itself was implicated in the prolonged sensation of pain caused by acidosis.

The invention also relates to a hybrid cationic channel constituted by the combination of a first protein constituting a proton-activated ionic channel according to the invention with a second protein constituting a proton-activated ionic channel. Advantageously, the said second protein is also a protein constituting a proton-activated ionic channel according to the invention. As an example of such a combination, one can cite the combination of the protein of the ASIC1A or ASIC2A or DRASIC channel with the protein of the MDEG1 channel, enabling formation of a hybrid channel exhibiting a third range of pH sensitivity (with ASIC: EC₅₀ = 4.8). Another example of such a hybrid channel is the combination of the protein of the ASIC1A, ASIC1B, MDEG1 or DRASIC channels with the protein of the MDEG2 channel.

MDEG2 is a channel that was cloned from the rat brain using a partial mouse sequence accessible in the data banks ("Expressed Sequence Tag with accession number W50528") and whose sequence of 563 amino acids is represented in the annexed list of sequences under number SEQ ID NO: ¹²~~6~~.

MDEG2 is a splicing variant of MDEG1. The first 185 amino acids are replaced by a new sequence of 236 amino acids which is underlined in SEQ ID NO: ¹²~~6~~. MDEG2 is expressed in the brain and in the sensory neurons of the dorsal root ganglia.

MDEG2 expressed alone in *Xenopus* oocytes or in mammal cells does not form a proton-activated cationic channel. However, it can combine with MDEG1 or DRASIC to form proton-activated heteromultimeric channels with modified properties:

5 – The activation pH of the channel formed after the co-expression of MDEG1 and MDEG2 is different. After expression in COS cells, the current has not reached its maximum value at pH 3 whereas the current induced by MDEG1 alone is saturated at a pH between 4.5 and 4.0.

10 – The inactivation kinetics and the ionic selectivity of the channel formed after the co-expression of MDEG1 and MDEG2 are clearly different from those of MDEG1 alone. A current appears which inactivates itself slowly and is barely selective for Na⁺ and K⁺.

15 – The sodium current obtained after expression of DRASIC becomes non-selective (it does not differentiate between sodium and potassium) when MDEG2 is co-expressed with DRASIC. This new property is similar to that of the proton-activated cationic channel which is implicated in the prolonged sensation of pain caused by acidosis. It is very probable that DRASIC and MDEG2 are part of this channel.

20 The amino acid sequence homologies of the proteins constituting the ASIC1A, ASIC1B channels cited according to the invention are presented in table 1 below.

Table 1

Channel	ASIC 1B	ASIC 1A	MDEG2	MDEG1	DRASIC
ASIC1B	100	80	56	61	52
ASIC1A		100	59	68	53
MDEG2			100	78	48
MDEG1				100	51
DRASIC					100

Polyclonal or monoclonal antibodies directed against at least one protein
 5 constituting an ionic channel of the invention and/or against a hybrid chan-
 nel as above can be prepared by the classic methods described in the literature.
 The antibodies are useful for investigating the presence of the ionic channels
 of the invention in various human and animal tissues, but due to their speci-
 ficity they can also find applications in the therapeutic domain for inhibiting
 10 or activating *in vivo* an ASIC channel and/or its derivatives.

The present invention also has as its object a nucleic acid molecule com-
 prising or constituted by a nucleic sequence coding for a protein constituting a
 neuronal cationic channel that is sensitive to amiloride and activated by pro-
 tons. More particularly, the invention relates to a nucleic acid molecule
 15 comprising at least one sequence coding for the protein constituting the ASIC
 channel whose amino acid sequence is represented in the annexed list of se-
 AA quences under number SEQ ID NO: ~~1~~² or for a functionally equivalent deriva-
 tive of this protein. A DNA molecule comprising the sequence coding for the
 ASIC protein is the one represented in the annexed list of sequences under
 AA 20 number SEQ ID NO: 1 or its complementary sequence. Another DNA mole-
 cule according to the invention is the one represented in the annexed list of
 AA sequences under number SEQ ID NO: ~~2~~³ or under number SEQ ID NO: ~~3~~⁵ or
 their complementary sequence.

Sur c1 A DNA molecule comprising the sequence coding for the ASIC1B protein is that of 3647 pb represented in the annexed list of sequences under number SEQ ID NO: 4 or its complementary sequence. More specifically, the invention relates to the nucleic sequence comprised between nucleotides 109 and 5 1785 of the sequence represented in the annexed list of sequences under number SEQ ID NO: 4 or its complementary sequence.

Sur c2 A DNA molecule coding for the DRASIC protein is that of 1602 pb represented in the annexed list of sequences under number SEQ ID NO: 5 or its complementary sequence.

Sur c3 A DNA molecule coding for the MDEG1 protein is that of 1602 pb represented in the annexed list of sequences under number SEQ ID NO: 6 or its complementary sequence.

The invention also relates to a vector comprising at least one of the preceding nucleic acid molecules, advantageously combined with suitable control sequences, as well as a procedure for production or expression in a cell 15 host of a protein constituting an ionic channel according to the invention. The preparation of these vectors as well as production or expression in a host of the channels of the invention can be implemented by means of the molecular biology and genetic engineering techniques known to the expert in the 20 field.

As an example, a production method for a protein constituting a cationic channel according to the invention is comprised of:

- transferring a nucleic acid molecule according to the invention or a vector containing said molecule into a cell host,

- culturing said cell host under conditions allowing production of the protein constituting the cationic channel,

- isolating by any suitable means the proteins constituting the ionic channels of the invention.

5 As an example, a method for expressing an ionic channel according to the invention is comprised of:

- transferring a nucleic acid molecule of the invention or a vector containing said molecule into a cell,

- culturing said cell host under conditions allowing expression of the 10 ionic channels of the invention.

The cell host employed in the preceding methods can be selected from among the prokaryotes or the eukaryotes and notably from among the bacteria, yeasts or cells of mammals, plants or insects.

The vector used is selected in relation to the host to which it will be transferred; any vector such as a plasmid can be used. 15

The invention thus also relates to the transformed cells expressing ASIC channels and/or its derivatives such as MDEG obtained according to the preceding methods. These cells are useful in screening for substances capable of modulating the perception of acidity with regard to both nociception and taste 20 transduction. This screening is implemented by bringing variable quantities of a substance to be tested into contact with cells expressing the ASIC channels then measuring, by any suitable means, the possible effects of said substance on the currents of said channels. Electrophysiological techniques also enable these studies and are also the object of the present invention when employ- 25 ing ASIC channels or their derivatives. These screenings allow identification of new drugs that are useful in the treatment or prevention of pain. They

also enable investigation of agents that modulate acid taste. In addition, they enable investigation of blockers that can inhibit neurodegenerations induced by hyperexpression of these channels. These drugs which are isolated and detected by means of the methods above are also part of the invention. The ASIC channels clearly have ionic selectivity properties, notably with regard to their selective permeability by sodium, potassium and calcium, which endows them with excitotoxic properties when hyperstimulated.

A protein constituting an ASIC neuronal ionic channel can also be useful for the fabrication of drugs intended for the treatment or prevention of pathologies entailing the painful perception of acidity which intervenes in inflammatory diseases, ischemias and a certain number of tumors. The invention thus also relates to the pharmaceutical compositions comprising as active ingredient at least one protein constituting an ionic channel according to the invention.

A nucleic acid molecule coding for a protein constituting an ASIC channel or a derivative thereof, or a vector comprising this nucleic acid molecule or a cell expressing ASIC channels are also useful for the preparation of transgenic animals. These can be animals superexpressing said channels, but especially so-called "knock-out" animals, i.e., animals presenting with a deficiency in these channels; these transgenic animals are prepared by methods known to the expert in the field, and enable production of live models for studying animal pathologies associated with the ASIC channels.

The nucleic acid molecules of the invention or the cells transformed by said molecule can thus be used in genetic therapy strategies in order to compensate for a deficiency in the ASIC channels at the level of one or more tissues of a patient. The invention thus relates also to a drug comprising nucleic acid molecules of the invention or cells transformed by said molecules

for the treatment of pathology involving the ASIC channels or their derivatives.

In addition to the property of being activated by protons and the resultant applications described above in the domain of the perception of acidity, the ASIC channel, because of its structural relationship with the MDEG channel, can act like a neuronal degenerine following mutation.

The death of certain neurons is characteristic of many types of neuronal degenerative disorders such as Alzheimer's disease, Huntington's disease, Parkinson's disease, amyotrophic lateral sclerosis and cerebellar ataxia. Only a few deficient genes are known and many more remain to be identified. The primitive neural network of the nematode *C. elegans* constitutes a good model of neuronal development and death. The hereditary degeneration in *C. elegans* can be due to mutations of the degenerines deg-1, mec-4 and mec-10. The homologies with the subunits of the amiloride-sensitive sodium channel, the functional expression product of the mec-4 chimeras of the epithelial sodium channel, suggest that the degenerines are ionic channels whose acquisition of function is the cause of neuronal degeneration.

The present invention thus also relates to application of the ASIC channel for studying these pathological modifications that lead to degenerations. The techniques employed for these applications, for example for drug screening, are similar to those described above for the investigation of taste-modulating agents and analgesic agents.

In addition, a protein constituting an ASIC neuronal ionic channel, an agonist or an antagonist of said protein, can also be used for the fabrication of drugs intended for the treatment or prevention of pathologies involving cerebral neuronal degeneration. The invention thus also relates to the pharmaceutical preparations comprising as active ingredient at least one of these proteins possibly combined with a physiologically acceptable vehicle.

More specifically, the invention relates to a chemical or biological substance that is capable of modifying the currents of an ionic channel and/or a hybrid channel according to the invention for the preparation of a drug capable of modulating the perception of acidity with regard to nociception as well as taste transduction in a human or animal subject.

Summary Other characteristics and advantages of the invention will be seen in the description below related to research activities that led to the demonstration and the characterization of the ASIC channel, and in which reference will be made to the annexed sequences and drawings in which:

- SEQ ID NO: 1 represents the sequence of 526 amino acids of the protein of the ASIC channel deduced from the cDNA sequence of the rat.

- SEQ ID NO: 2 represents the partial sequence of 514 amino acids of the protein of the ASIC channel deduced from the partial sequence of human cDNA.

- SEQ ID NO: 3 represents the sequence of 512 amino acids of the protein of the MDEC channel deduced from the sequence of human cDNA.

- SEQ ID NO: 4 represents the sequence of 559 amino acids of the protein of the ASIC1B channel as well as the sequence of a DNA molecule comprising the sequence coding for that protein.

– SEQ ID NO: 5 represents the sequence of 533 amino acids of the protein of the DRASIC channel and the sequence of DNA coding for that protein.

– SEQ ID NO: 6 represents the sequence of 563 amino acids of the protein of the MDEG2 channel as well as the sequence of a DNA molecule comprising the sequence coding for that protein.

– Figure 1 represents the alignment of the sequences of the rat ASIC proteins (at top) and human ASIC proteins (at bottom) of sequences SEQ ID NO: 1² and SEQ ID NO: 2⁴. Comparison of these sequences shows the absence of 14 amino acids at the beginning of the human coding phase compared to that of the rat.

Figure 2 represents a comparison of the protein sequence of the ASIC channel with the sequence of other ionic channels:

– MDEC [14], a mammalian cationic channel that is activated by the mutations responsible for neurodegenerations with the degenerines of *C. elegans*.

– FaNaCh [10], a peptide of a sodium channel of *Helix aspersa* that is activated by FMRFamide.

– The degenerine MEC-4 [12] of *C. elegans*.

In this figure, the residues that are identical or similar to those of ASIC are printed respectively in white on a black background and in black on a gray background. The supposed transmembranal regions (MI, MII) of ASIC are marked by black bars.

Figure 3 represents the phylogenetic tree of the proteins of the subunits α NaCh, β NaCh, γ NaCh, δ NaCh of the amiloride-sensitive sodium channel and of the degenerines MEC-4, MEC-10 and DEG-1 of *C. elegans*.

Figure 4 represents the topology proposed for this latter family of ionic channels [30].

Figure 5 shows the biophysical properties of the proton-activated ASIC1 channel.

– In a: the macroscopic inflowing currents recorded at -70 mV after rapid pH changes from pH 7.4 to pH 6.

5 – In b: The dose-response curve of the extracellular pH. The initial pH was 7.4 and the points represent the mean values from 6 tests. The insert in this figure shows the typical responses at -70 mV.

10 – In c: the Q-V relations of the outside-out patch with 140 mM of Na⁺ (■) or of Li⁺ (•) in the bath solution. Q is the charge transported during the acid pH transition. The insert in this figure shows the typical responses in a medium containing Na⁺.

– In d: the currents activated by the H⁺ protons recorded at various potentials in an outside-out patch in a medium containing Na⁺.

15 – In e: the mean i-V relations measured from the outside-out patch with 140 mM of Na⁺ (■), 140 mM of Li⁺ (•) or 1.8 mM of Ca²⁺ (▲), as majority permeable ions in the external solutions; the inversion potentials were respectively 65 mV, 58 mV and -34 mV.

20 – In f: the proton current through the ASIC1 channel. The relations between the current peak and the voltage were measured from an outside-out patch in a solution of free Na⁺, free Ca²⁺ with pipettes containing a solution of free K⁺, at pH 4 (•) and at pH 3 (■), with (▲) representing the results obtained under the same conditions as (■) but with KCl in the pipette. The insert in this figure shows the typical responses under (▲) conditions.

Figure 6 shows the effect of Ca²⁺ and of amiloride on the ASIC current.

- In a: the currents activated by the H^+ protons recorded at various mem-
branal potentials from an outside-out patch with 1.8 mM of Ca^{2+} in a solution
of free Na^+ ; the currents were inverted at -35 mV.

5 - In b: the mean Q-V relations from an outside-out patch recorded in solu-
tions of free Na^+ containing 1.8 mM of Ca^{2+} (o, inversion potential -34 mV) or
0.1 mM of Ca^{2+} (•, inversion potential -80 mV).

- In c: the effect of the external Ca^{2+} on the macroscopic peak of inflowing
current recorded at -70 mV and activated by a rapid pH change from pH 7.4 to
pH 6. The insert in this figure shows the typical responses. The points repre-
10 sent means values \pm se of 5 oocytes.

- In d: the effect of amiloride on the currents activated by the H^+ protons
recorded at 0 mV from an outside-out patch.

- In e: the inhibition of the macroscopic current (induced by a pH change
from pH 7.4 to pH 6) at -70 mV by amiloride and derivatives. The points rep-
15 resent the means values \pm se of 5 oocytes.

Figure 7 shows the tissue distribution of ASIC channel mRNA.

- In a: Northern blot analysis of the mRNA expression of the ASIC chan-
nel in human tissues.

- In b: RT-PCR analysis of the mRNA expression of the ASIC channel in
20 the rat brain and in the dorsal root ganglion (DRG). (+), (-) represent respec-
tively the samples with or without reverse transcriptase. The agarose gel sec-
tions were developed in 1% ethidium bromide. The arrows indicate the dis-
counted size (657 pb) of the PCR product.

Figure 8 represents the *in situ* hybridization.

– In a and b: hybridization of 6- μ m sections of a dorsal root ganglion from a 3-year-old rat with the E probe marked with digoxigenin. In a: a low-lighting microphotograph (enlargement 30 X). In b: a high-resolution image (enlargement 80 X) of a: One can see the intense marking of the small-diameter neurons (arrows). Similar results were also obtained with probes A, C and D.

– In c: the distribution of the ASIC channel mRNA in the brain of an adult rat analyzed by in-situ hybridization with antisense oligonucleotide C. Identical results were obtained with oligonucleotide B. The colors indicate abundance (red: high expression; blue: not detectable). The abbreviations used in the figure are as follows: Cer = cerebellum; Hip = hippocampus; OB = olfactory bulb; Cx = cortex.

I - Materials and Methods

1) Cloning the ASIC channel.

The conserved sequences of the family of ASIC ionic channels were used to prepare the following PCR primer sequences:

AA TTYCCIGCIRTIACIITNTGYAAY_^ and (Seq ID: 15)
AA CAIARICCIAIITGNCCNCCDAWRTC_^ (Seq ID: 16)

A bank of rat brain cDNA (Stratagène #936515) was hybridized with the PCR product of 1 kB of rat brain and the partial clones were isolated. The fifth extremity of the cDNA (202 bp) was isolated by PCR after ligation adapted to the double-strand cDNA.

2) Electrophysiology

0.25 ng of cRNA was injected into the *Xenopus laevis* oocytes and the recording microelectrodes for the imposed voltage and for the patch-clamp

were installed two days after the injection. The bath solutions for the outside-out patch recordings and the pipettes for the outside-out patch and total cells recordings contained: 140 mM KCl (or NMDG), 2 mM $MgCl_2$, 5 mM EGTA, 10 mM Hepes, pH 7.4 (with KOH). The pipettes for the outside-out patch recordings and the bath solutions for the outside-out patch and total cells recordings contained: 140 mM NaCl (or LiCl or NMDGCl), 2 mM $MgCl_2$, 1.8 mM $CaCl_2$, 10 mM Hepes, pH 7.4 (adjusted with HCl, NaOH, LiOH or TMAOH). The rapid pH changes from the initial pH were obtained by perfusion with a bath solution adjusted to the pH indicated in the figures. The intracellular acidification of the oocytes was implemented by injecting 50 nl of the internal solution at pH 2 or by perfusion and withdrawal of a bath medium containing 20 mM NH_4Cl . None of the recorded currents was contaminated by the Ca^{2+} current sensitive to the Cl^- of the *Xenopus* oocyte. The data were sampled at 2 kHz and filtered at 500 Hz for the analysis (Logiciel Biopatch).

3) Northern blot analysis, RT-PCR and *in-situ* hybridization

The Northern blot kit was obtained from Clontech Co. (Palo Alto, CA) and contained circa 2 μ g of poly(A⁺) RNA per line. The blot was hybridized with a fragment of the partial human clone (corresponding to bases 270 to 764 of the rat clone) marked with ^{32}P at 65°C in 6xSSC. For the RT-PCR analysis, 5 μ g of rat brain total RNA and 3 μ g of dorsal root ganglion were reverse transcribed and 1/30 of the sample was amplified by 30 PCR cycles with the following sequence primers:

AA ATTGCTCTTCCCATCTCTAT, and
 AA TTCAAGGCCCATACCTAAGT.

(Sequid 10:11)
 ^
 ^ (Sequid 10:12)
 ^

The negative controls were treated in an identical manner with the exception of the reverse transcriptase which was not added. The antisense oligonucleotides corresponding to base 70 to 114 (A), 215 to 248 (B), 1821 to 1859 (C), 1396 to 1940 (D) and the double-strand DNA corresponding to base 1685 to 2672 were used for the *in-situ* hybridizations. The sections of adult rat brain were hybridized with oligonucleotides B or C the ends of which were marked with ^{32}P for one night at 37°C in 50% formamide, 2xSSC, then washed at ambient temperature in 1xSSC. The signal was eliminated by 500-times excess of unmarked oligonucleotides. The dorsal root ganglion sections were hybridized with oligonucleotides A, C or D marked with digoxigenin (DIG)-dUTP and with probe E marked with DIG-dUTP by PCR. The marking of the probes, the preparation of the samples, the hybridization and the visualization of the DIG nucleic acids with alkaline phosphatase conjugated with anti-DIG antibodies were performed in accordance with the supplier's protocols (Boehringer Mannheim).

4) Computer analysis

The sequence alignments and the phylogenetic tree (Kimura substitution, UPGMA option) were performed with the GCG program (Genetics Computer Group, Madison, WI).

20 II – Results

The 35 kb cDNA isolated from rat brain codes for a protein of 526 amino acids that exhibits, as shown in figure 2, homologies with all of the cloned members of the family of amiloride-sensitive degenerine sodium channels.

As shown in figure 5, expression of the cRNA in the *Xenopus* oocytes induced an inflowing current activated by H^{+} protons. The biophysical and pharmacological properties of the ASIC channel are close to those described

for the proton-activated cationic channels of sensory neurons [3, 15, 16]. Reduction of the extracellular pH below a pH of 6.9 activates a rapidly rising and desensitized inflowing current (figure 5a and b). This channel is activated by extracellular protons since, as shown in figure 5 (c and d), application of an acid on the extracellular surface of the outside-out patch activates the channel. Intracellular acidification of oocytes and acidification of the intracellular surface of the outside-out patch does not activate the ASIC channel nor alter the ASIC current induced by the extracellular protons.

The analysis of curves I-V of figure 5 (c and e) recorded with different extracellular cations shows that Na^+ is the majority permeable ion (simple conductance channel 14.3 pS). Like the proton-sensitive ionic channel of the sensory neurons [15, 16], the ASIC channel discriminates weakly between the cations (figure 5c, e, f). In fact, the channel is also permeable to Li^+ , K^+ , Ca^{2+} and H^+ with the ratios $\text{pNa}^+/\text{pLi}^+ = 1.3$ (figure 5c, e), $\text{pNa}^+/\text{pK}^+ = 13$ (figure 5c, e), $\text{pNa}^+/\text{pCa}^{2+} = 2.5$ (figure 5e) and $\text{pNa}^+/\text{pH}^+ = 0.8$ (figure 5f). The permeability to Ca^{2+} of ASIC could be a voltage-independent entry path of Ca^{2+} into the cell. An inflowing current of Ca^{2+} into the cell via the ASIC channels can be detected in the absence of extracellular Na^+ (figure 6a, b). As indicated in figure 5 (e), the unitary conductance for Ca^{2+} was 5.2 pS. In the presence of 140 mM of extracellular Na^+ , augmentation of the concentrations of external Ca^{2+} diminished the amplitude of the current activated by the protons (Figure 6c), thereby demonstrating that Ca^{2+} inhibits the permeability to Na^+ . Blockage by external Ca^{2+} is characteristic of the $\text{I}(\text{H}^+)$ of the sensory neurons [17]. The inflowing current activated by H^+ in the sensory neurons is inhibited by amiloride [18] and ethylisopropylamiloride (EIPA) [19]. As shown in figure 6 (d, e), the ASIC channel exhibits the same pharmacology and is blocked in a reversible manner ($K_d = 10 \mu\text{M}$) by amiloride and its derivatives benzamil and EIPA.

In addition, the ASIC channel protein exhibits approximately 67% sequence homology with the degenerine ionic channel referred to as "MDEG" [14] or "BNaCl" [20]. However, the electrophysiological properties of these two clones expressed in *Xenopus* oocytes are clearly different:

5 – As shown in figure 5a, the MDEG channel is not activated by the same pH changes as the ASIC channel.

 – Substitution of the glycine residue in position 430 of MDEG by an acid-inhibiting amino acid such as valine or phenylalanine activates the channel [14], just as the mutation of alanine in position 704 of degenerine MEC-4
10 causes neurodegeneration in *C. elegans* [12]. Identical mutations of ASIC (glycine in position 431 replaced by valine or phenylalanine) do not lead to activity and the mutants can not be activated by protons.

 Proton-activated cationic channels have been described not only in the sensory neurons but also in the neurons of the central nervous system [21].
15 The tissue distribution of the expression of the mRNA of the ASIC channel is in agreement with this observation. As shown in figure 7a, a 4.3-kb transcript was detected in the brain by Northern blot analysis and the PT-PCR results presented in figure 7b show that the dorsal root ganglion expresses the ASIC mRNA. Figure 8 (a, b) shows that ASIC mRNA is well expressed by the small
20 neurons of the dorsal root ganglion, which supports the fact that ASIC is the rapidly desensitizing proton-activated cationic channel described in the nociceptive sensory neurons. Whereas the presence of proton-activated cationic channels in the dorsal root ganglion is in agreement with their function of acidity detector in nociception, their role in the brain remains to be estab-
25 lished. The results of *in-situ* hybridization in figure 8c show a broad and heterogeneous expression of the ASIC channel mRNA. The highest levels of expression were observed in the principal olfactory bulb, the cerebral cortex,

the hippocampus, the habenula, the basolateral amygdaloid nucleus and the cerebellum. The synaptic activity accompanies extracellular pH changes [22, 23] and the rapid localized pH changes in or close to the synaptic cleft are noticeably more saturated and stronger than the reported macroscopic fluctuations in the pH.

The proton-activated cationic channels are the only known ionic channels that are directly activated by a change in pH and it was envisaged that the extracellular fluctuations in pH played a neuromodulator role [23]. The expression of cationic channels in the brain supports in addition the hypothesis that the pH fluctuations are not solely a neuronal activation by a product, but even more a communications pathway in the central nervous system.

In addition to the rapidly inactivated proton-activated cationic channels, the presence has been reported in the sensory neurons of proton-activated cationic channels exhibiting slower kinetics [4, 24]. The proton-activated cationic channels probably form, like other cationic channels activated by a ligand [25, 26], a family of cationic channels in which different subunits or combinations of subunits constitute channels with diverse pharmacological and biophysical properties.

The sensation of acidity is not uniquely implicated in nociception but is also associated with the transduction of taste [2]. Acid stimulations activate the proton-activated cationic channels in the taste cells [2, 27] and amiloride inhibits the perception of acid taste [2]. Also, the physiological as well as pharmacological data indicate that ASIC and other member of this family are implicated in the transduction of taste. It is, in fact, especially surprising that the same class of ionic channels is associated with different facets of sensory perception:

– The amiloride-sensitive sodium channels are associated with the transduction of salty taste [2].

– The degenerines of *C. elegans* are implicated in mechanotransduction and have been proposed as forming the mechanosensitive ionic channels [28, 29].

– The ASIC channels are implicated in nociception and the transduction of acid taste.

Cloning of the ASIC channel provides a new tool for the investigation of this group of ionic channels and the development of specific blockers for use notably as analgesic agents.

cont.

INFORMATION CONCERNING SEQ ID NO: 1

- i) CHARACTERISTIC OF THE SEQUENCE:
 - A) LENGTH: 3562 base pairs
 - B) TYPE: nucleic acid
 - C) NUMBER OF STRANDS: double
 - D) CONFIGURATION: linear
- ii) TYPE OF MOLECULE: DNA
- vi) ORIGIN: rat
- ix) CHARACTERISTIC
 - A) NAME/KEY: ASIC
 - B) LOCALIZATION: 123 .. 1700
- xi) DESCRIPTION OF THE SEQUENCE: SEQ ID NO: 1:

Top of page 28 =

INFORMATION CONCERNING SEQ ID NO: 2

- i) CHARACTERISTIC OF THE SEQUENCE:
 - A) LENGTH: 1620 base pairs
 - B) TYPE: nucleic acid
 - C) NUMBER OF STRANDS: double
 - D) CONFIGURATION: linear
- ii) TYPE OF MOLECULE: DNA
- vi) ORIGIN: human
- ix) CHARACTERISTIC
 - A) NAME/KEY: ASIC
 - B) LOCALIZATION: 1 .. 1542
- xi) DESCRIPTION OF THE SEQUENCE: SEQ ID NO: 2:
